

Bolt that can be pressed into a metal sheet in a torsion-  
proof and ejection-proof manner.

The present invention relates to a bolt that can be pressed  
into a metal sheet in a torsion-proof and ejection-proof man-  
ner according to DE-Gbm 200 12 097 U1.

Since during the setting of bolts according to this refer-  
ence, on the one hand, is accompanied by a flowing of the ma-  
terial of the metal sheet, on the other hand, however, a  
sealing only is consisting of a steel-steel material pairing,  
the connection between the bolt and the metal sheet according  
to the prior art is not safely tight against liquid or even  
gases.

It is therefore the task to be solved by the present inven-  
tion to improve such a bolt in such a way that after the set-  
ting it is positioned in a fluid- and gas-tight manner.

In this way, according to the invention, for the first time,  
such a bolt that can be pressed-in could be used in cases  
where it is necessary that the bolt after the setting is ab-  
solutely liquid-tight and gas-tight.

Until now to this end only commercial screws could be used  
which therefore however in a expensive way singularly had to  
be welded, wherein during the welding, too, a substantial ex-  
penditure with respect to inspection was necessary to ensure  
that the welding always was gas-tight. Therefore this method  
was extremely complicated and cost-intensive. According to

the invention, this method in a far more simple way can be performed by pressing-in a bolt according to the invention.

5 The above-defined task therefore is solved by means of a bolt according to the preamble of the enclosed claim 1, wherein the side of the head facing the metal sheet is provided with a rubber-elastic sealing material.

10 Preferred embodiments can be learned from the enclosed sub-claims, wherein it is especially preferred that the webs themselves are free from the sealing material since in this way a decreasing of the safety against torsion and ejection of the bolt by the covering with the sealing material is avoided.

15 In the same way, this can be prevented by the sealing material being provided exclusively in the region of the outer rim of the head facing the metal sheet.

20 In the same way, this further problem can be avoided by the fact that the sealing material exclusively is positioned in an annular groove in the head which is positioned outwardly of the radial extension of the webs but within the outer edge of the head facing the metal sheet.

25 The present invention, in the following, is more detailly described with respect to the exemplary embodiments shown in the drawings. In the drawings show:

30 **FIGURE 1** a bolt according to the invention with a coating of the entire head except the webs in a lateral cross-sectional view;

FIGURE 2 the head of the bolt according to Figure 1 from below;

FIGURE 3 a bolt according to the invention with the sealing material in the region of the outer edge of the head in a lateral cross-sectional view;

FIGURE 4 the bolt of the head according to Figure 3 from below;

FIGURE 5 a further bolt according to the invention in a lateral cross-sectional view; and

FIGURE 6 the head of the bolt according to Figure 5 from below.

As shown in Figure 1, a bolt 10 according to the invention is consisting of a disk-shaped head 12 and a connected cylindrical winding support 14 having an exterior thread.

Between the thread and the head 12, in the following order a calibration collar 16, an annular projection 18 and an annular groove 20 having a semi-circular cross-section are provided. On the bottom side of the head 12, which is facing during the setting of the fastener the metal sheet, there are provided radially extending webs 22 having a radial extension in a basically uniform height and which merely in their radially exterior area 21 are flattened.

The head 12 is shown partly in cross-section, wherein on the right hand side the corresponding web 22 is shown in cross-section, too, while the corresponding web 22 on the left hand side is shown in a side view.

According to the invention, such a bolt can be set in a metal sheet in a fluid- and gas-tight manner by coating the head with a rubber-elastic sealing material. The coating can be performed in the most simple way by immersion, wherein the corresponding coating can be extended up to the calibration collar 16. As a coating material in this case preferably epoxy resin is used, for example the product Rimlex® of the ANOCHROME-Group, Great Britain, which can be applied in a liquid state which later is forming a solid elastic sealing material. In such a case, the safety with respect to torsion and ejection of the bolt can be impaired slightly. The coating 110 shown in Figure 1 therefore is extending only onto the head itself, wherein the webs 22 are kept free from the coating. This, on the one hand, is more difficult to be produced compared with the above-disclosed simple solution according to the invention, on the other hand, is providing for higher mechanical load values of the set bolt.

Figure 2 is showing the head 12 of the bolt according to Figure 1 from below. Because of the interrupted cross-hatching, the area provided with the sealing material 110 of the head 12 visible from below clearly can be seen. Equally clearly it can be seen that the webs 22 including their bevels 21 are not covered by the rubber-elastic sealing material.

Figure 3 is showing a further embodiment of the bolt according to the invention. Same reference numerals are characterising here the same constituents as in Figures 1 and 2 and the corresponding description here is not again repeated.

With respect to the bolt showing in Figure 3 according to the invention in the region of the outer edge of the head 12 facing the metal sheet a circumferential recess is provided being filled with the rubber-elastic sealing material 120. Al-

ternatively a corresponding sealing ring of polyurethane, polyamide, polytetrafluorethylene or polyolefins can be inserted into the recess. This solution has the advantage that the mechanical properties of the set bolt are not at all influenced by the sealing material.

Figure 4 is showing the head of the bolt of Figure 3 from below, wherein the position of the annulus 120 of the rubber-elastic sealing material again clearly can be learned.

Figure 5 is showing a further embodiment of the bolt according to the invention. Here the head 12 is having a slightly larger diameter and radially outwardly of the webs 22 an annular groove 134 is provided in the head 12 which therefore is extending within the outer edge 132 of the head 12 facing the metal sheet. This groove 134 is filled with the sealing material 130 or a corresponding sealing ring of polyurethane, polyamide, polytetrafluorethylene or polyolefins is inserted in the groove 134.

Figure 6 is showing the head of the bolt of Figure 5 from below. Here again the extension of the annular groove 134 is obvious.

As a rubber-elastic sealing material 110, 120, 130 here preferably when coating the head epoxy resin is used, wherein in connection with the solutions according to Figures 3 or 5 preferably polyurethane, polyamide, polytetrafluorethylene or a mixture of polyolefins is used.
